Abstract

The inconsistent definition of empathy has had a negative impact on both research and practice. The aim of this paper is to review and critically appraise a range of definitions of empathy and, through considered analysis, to develop a new conceptualisation. From the examination of forty-three discrete definitions, eight themes relating to the nature of empathy emerged: ‘Distinguishing Empathy from Other Concepts’; ‘Cognitive or Affective? ’; ‘Congruent or Incongruent?’; ‘Subject to Other Stimuli?’; ‘Self-other Distinction or Merging?’; ‘Trait or State Influences?’; ‘Has a Behavioural Outcome?’; and ‘Automatic or Controlled?’ The relevance and validity of each theme is assessed and a new conceptualisation of empathy is offered. The benefits of employing a more consistent and complete definition of empathy are discussed.

Keywords: empathy; definition; cognitive empathy; affective empathy; empathy assessment
The term ‘empathy’ was coined over one hundred years ago by Titchener, an adaptation of the German word *Einfühlung* (Wispé, 1986). According to Stotland and colleagues, discussions of empathy may even date back to “the beginnings of philosophical thought” (Stotland, Matthews, Sherman, Hansson, & Richardson, 1978). Despite this extensive history, empathy is not a well defined notion. Instead, there are perhaps as many definitions as there are authors in the field (Decety & Jackson, 2004; de Vignemont & Singer, 2006).

Several problems result from this fact. Firstly, when interpreting research findings relating to ‘empathy’, one must first determine precisely what is being studied, and the degree of confusion with related concepts. This can make the interpretation of outcomes difficult, compromising the comparability of studies (Brown, Harkins, & Beech, 2012; Gerdes, Segal, & Lietz, 2010). Secondly, there appear to be differences in the way researchers and practitioners conceptualise empathy (Mann & Barnett, 2012), leading to a mismatch between the way empathy is researched and dealt with in treatment and education programmes that aim to enhance empathy. Thirdly, therapeutic difficulties can arise when concepts are understood differently (Book, 1988; Clark, 2010), with some understandings of empathy having greater therapeutic effectiveness than others (see Clark, 2010; Nightingale, Yarnold, & Greenberg, 1991). These issues, and suggestions for their resolution, are discussed further towards the end of this paper.

While definition diversity should not necessarily be discouraged (e.g., Duan & Hill, 1996), efforts should be made to draw together knowledge to improve our understanding and to reduce confusion in the field. Although “there is no way to ascertain which definition is correct” (Eisenberg et al. (1991, 64), it is possible to compare and contrast how empathy is conceptualised, and discuss any differences, examining competing viewpoints in light of the
EMPATHY: A REVIEW OF THE CONCEPT

current knowledge-base. The purpose of this paper is to explore the range of current conceptualisations of empathy and present a discussion outlining similarities that are supported in the literature, and to formulate a new conceptual summary of empathy that can be used by future researchers/practitioners.

**Identifying Areas of Confusion**

A snowballing procedure was employed to identify definitions in the literature from key papers, and exploring avenues of interest from reference lists. This process was not intended as an exhaustive review, but was designed to capture definitions across a range of different viewpoints. Only English language papers were examined, as there was no provision for translation of non-English language sources.

A total of forty-three distinct definitions/conceptual summaries were identified (see Table 1). A small number of these conceptualisations were not put forward by authors as formal ‘definitions’, but were summary statements of the wider theoretical discussions of empathy. These informal methods of defining empathy were nevertheless reviewed alongside the formal definitions as they have the same relevance in terms of interpreting and understanding research findings. The present discussion is based upon shorthand conceptualisations (definitions) of empathy, rather than full-fledged models, for two reasons. Firstly, many models of empathy focus upon the wider empathic process (i.e., the process from perception to behaviour), which is beyond the scope of this paper. Secondly, this method allowed us to capture a wider range of ideas and theoretical positions, as the majority of definitions are presented in the literature without such models. The conceptualisations identified are numbered in Table 1; to avoid lengthy citations, in the following discussion these conceptualisations are referred to using superscript numbers relating to their position in Table 1.
By breaking each definition down into individual clauses and examining similarities and differences, eight themes crucial to our understanding of the concept were identified and are discussed below.

**Distinguishing Empathy from Other Concepts**

Several notable attempts have been made to differentiate empathy from a range of associated concepts (see Batson, 2011; Eisenber, Shea, Carlo, & Knight, 1991; Scheler, cited in Becker, 1931). Others (e.g., Batson, Fultz, & Schoenrade, 1987; Preston & de Waal, 2002) denote empathy as an overarching category, containing all associated concepts such as emotional contagion, sympathy, and compassion. To explain why empathy is commonly merged with associated terms, Ickes (2003) utilised Scheler’s (cited in Becker, 1931) discussion on the related concepts of compathy (shared feelings due to shared circumstances), empathy (understanding another’s emotions through perspective taking), mimpathy (imitating another’s emotions, without experiencing them oneself), sympathy (intentionally reacting emotionally), transpathy (emotional contagion, where one is ‘infected’ by another’s emotions), and unipathy (an intense form of transpathy). According to Ickes, such terms differ across three dimensions: the degree of cognitive representations of the target’s emotional state; the degree of emotion sharing; and the degree to which a self-other distinction is maintained. Ickes noted that empathy is located in the mid-range for all three of these dimensions, and that the meaning of this term “has an inherent ambiguity that invites the kind of definitional debates that have continued since the term *Einfühlung* was first
introduced nearly a century ago.” Nevertheless, Ickes (and Scheler) claimed that although such terms are related, there is an argument for their separation.

Perhaps the most frequent discussion with regards to this theme is the difference between empathy and sympathy. Several definitions appear to merge concepts of empathy and sympathy, or at least do not make this distinction clear, whilst others argue against merging sympathy and empathy (e.g., Eisenberg et al., 1991; Hein & Singer, 2008; Scheler, cited in Becker, 1931). Eisenberg et al. (1991, p.65) defined sympathy as “a vicarious emotional reaction based on the apprehension of another’s emotional state or situation, which involves feelings of sorrow or concern for the other”. The distinction between empathy and sympathy has been described as “feeling as and feeling for the other”, respectively (Hein & Singer, 2008, p.157; emphasis in original). For example, when perceiving sadness in another, empathy will cause sadness in the observer (same emotion; feeling as), while sympathy will entail feelings of concern (different emotion; feeling for) (Singer and Lamm, 2009). This is consistent with reported differences in the neurological processes underlying the two constructs (Decety and Michalska, 2010). Due to these distinct emotional implications, it is the current authors’ view that empathy and sympathy should be separated. The emotion of ‘feeling for’ another deserves a name and given its current treatment in the literature by many authors, ‘sympathy’ lends itself as the most appropriate at this time.

Two other constructs commonly equated with empathy are compassion (“the feeling that arises in witnessing another’s suffering and that motivates a subsequent desire to help”; Goetz, Keltner, & Simon-Thomas, 2010, p.351) and tenderness (an expansive, “warm-and-fuzzy” feeling often elicited by the delicate and defenceless; Lishner, Batson, & Huss, 2011, p.615). It is possible to differentiate tenderness, compassion, and sympathy. Tenderness has been linked to vulnerability in the target (i.e. a long-term need), whereas the motivation
resulting from sympathy is targeted towards a current need (Lishner et al., 2011). While the distinction concerning compassion is less clear one suggestion is that compassion is a higher-order construct, consisting of feelings of sympathy and pity (Goetz et al., 2010). As such terms are more concerned with one’s feelings towards the other’s plight, rather than the sharing of emotions, they are more closely related to sympathy than empathy (Kalawski, 2010; Lishner et al., 2011; Nakao & Itakura, 2009).

**Cognitive or Affective?**

Perhaps the most discussed aspect of empathy is whether it is a cognitive or affective concept. Cognitive empathy is the ability to understand another’s feelings, related closely to theory of mind (Blair, 2005). Affective empathy is concerned with the experience of emotion, elicited by an emotional stimulus. Some definitions are based upon only affective, or cognitive, components. However, many definitions include both.

Research on personality and developmental disorders suggests that cognitive and affective empathy reflect two different constructs. For example, those with autistic spectrum disorder often appear to have cognitive empathy deficits, but average levels of affective empathy (Baron-Cohen & Wheelwright, 2004). Psychopathic individuals show the opposite pattern (Blair, 2005). Numerous neurological studies have also demonstrated distinct brain regions associated with each construct (e.g., Shamay-Tsoory, Aharon-Peretz, & Perry, 2009; Zaki, Weber, Bolger, & Ochsner, 2009). Nevertheless, due to extensive interaction, separation of the two concepts has been rejected (Baron-Cohen & Wheelwright, 2004; Duan and Hill, 1996; Singer, 2006). For example, Lamm, Batson, and Decety (2007) suggested that while affective empathy is automatically elicited, manipulation of cognitive elements can modulate affective elements. Given the above discussion, an appropriate viewpoint might be
that of Heberlein and Saxe (2005), in that whilst the affective and cognitive components can be separated, it is important to remember the interaction between the two processes. To give another perspective, Strayer (1987) suggested that the affective component is the content of empathy, whereas the cognitive component is the process via which this content is formed.

A further point to consider is whether empathy is necessarily restricted to an emotional context, or whether cognitive empathy can be considered ‘empathy’ alone. For example, cognitive-only empathy could help therapists understand clients’ thoughts and meanings, and teachers to recognise a lack of understanding in pupils (see Rogers, 1967; 1975). However, although inferring understanding and meaning in others uses very similar processes to cognitive empathy (e.g., perspective taking), the lack of interaction with any affective processes seems inconsistent with the widely accepted view of empathy as an emotional event (explicitly stated or implied by the majority of conceptualisations identified here). To avoid confusion, we recommend a different term for such scenarios, such as Empathic Understanding (Rogers, 1967).

Another debate relates to whether cognitive empathy and perspective taking (i.e., taking the perspective of the target, adopting their point of view) are the same construct. Several authors suggest they are. Nevertheless, there are notable counterarguments. For example, while perspective taking is important for theory of mind processes (Gery, Miljkovitch, Berthoz, & Soussignan, 2009), and is one method of achieving cognitive empathy, the two processes may not be one and the same. There are other ways of understanding another’s feelings without taking their perspective, such as reading facial expression (Besel & Yuille, 2010), accessing relevant memories of previous emotional situations (Eisenberg, 1986), imagining events in another place or time (Stinson & Ickes, 1992) and projection, where the observer assumes the target’s emotional state to be the same as his/her own (Nickerson, 1999; Nickerson, Butler, & Carlin, 2011; Preston, 2007).
Congruent or Incongruent?

Some authors have explicitly argued that the empathic emotion of the observer needs to be congruent with that of the observed individual \(^1,6\), with several implying this to be the case with a “sharing” of emotions \(^8, 16, 22, 27, 31, 32\), or “experiencing” the other’s emotions \(^2, 14, 20, 30\) vicariously. For others, congruency may occur but is not necessary\(^{13, 18, 32}\), and some authors suggest that the emotion is congruent with the observer’s perception of need or entitlement in the other\(^3, 5, 23\), thus congruent with the situation. Clearly there is a need to disambiguate this issue.

Some authors emphasise the importance of emotional congruency. For example, Rogers (1975, p.4) conceptualised empathy as “entering the private perceptual world of the other and becoming thoroughly at home in it”. Within a therapeutic relationship (which Rogers was primarily concerned with), one may be able to share and discuss emotions in depth. However, even the best therapist will be influenced by his/her own perspective, and the degree of congruency will depend upon this influence. Additionally, there are many examples outside of therapeutic relationships where empathy is felt without the opportunity for deep discussion of emotions (e.g. witnessing accidents), where the perspective and interpretation of the observer is the key source of information. Such perspectives and interpretations may or may not be accurate, and will be influenced by the observer’s thoughts (i.e., projection) and personality (Scheler, 1954; cited in Stotland et al., 1978), and by priming effects (Hodges & Biswas-Diener, 2007). Therefore, the degree of emotion matching will be dependent upon empathic accuracy: the ability to “accurately infer the specific content of another person’s successive thoughts and feelings” (Ickes, 2011, p.57).

Also arguing for emotional congruency, Hein and Singer (2008) suggested that congruency is what separates empathy (congruent) from sympathy (incongruent). This is consistent with the idea that empathy is related to the other’s feelings, while sympathy is a
reflection of one’s own (e.g., the feelings of concern that the observer holds for the target). However, this does not necessarily imply that the other’s emotion is a perfect match to one’s own. Levenson and Ruef (1992) argued that without accurate perception it will be difficult to respond compassionately. Presumably, however, an individual will respond based on his/her empathic experience, accurate or not. Naturally, cases of extreme incongruency, such as feeling anger as a result of mistaking sadness for anger in the target, will represent a failure of empathy.

According to de Vignemont and Singer (2006), neuroscientific evidence has yet to provide an answer to the debate on congruency, and testing for exact matching of emotion is nearly impossible (Preston, 2007). Nevertheless, the degree of congruency is dependent upon factors such as personal experience, imagination, simulation (Coplan, 2011) and the resources available for the verbal sharing of emotions. Accuracy is also dependent on how accurate the target is regarding his/her own emotions, which are often used as a measure of empathic accuracy (Batson, 2011). If the target fails to accurately decipher his/her own emotional state then the task of being empathically accurate is made more difficult for the observer. Each of these factors suggests that true empathic congruency will be difficult to achieve. Whilst the empathic emotion may be similar to the target’s, it is unlikely to ever be the same (Stotland et al., 1978).

**Subject to Other Stimuli?**

The previous discussion assumes that an emotional other is present for the observer to perceive. With a few exceptions, most authors make this assumption. However, some argue that direct perception may not be necessary. For example, Blair (2005) noted that empathy can either be in response to the emotions in another person or “other emotional stimuli” (p.699). Such stimuli may exist in three circumstances. First, it is possible
to encounter another person who has just experienced an emotional event (e.g., an accident), but who is minimising emotional cues (verbal, facial, etc.). We argue that observers may infer emotionality through perspective taking, imagination, or the retrieval of relevant memories. Neuroscientific evidence supports this contention as ‘intentional empathy’ (asking people to empathise with others) activates empathy-associated brain areas in the absence of emotional cues (de Greck et al., 2012). Second, empathy for an absent target may be elicited by verbal statements from a third party (Blair 2005; Polaschek, 2003), retrospectively (Barnett & Mann, 2013), and by inference from one’s previous experience (Eisenberg et al., 1991). Third, empathy can also be evoked by stimuli about a fictional or imaginary person (Decety & Jackson, 2004; Pelligra, 2011; Singer & Lamm, 2009). People respond emotionally to emotional scenes in books and animated films, where there are no living entities present experiencing an emotion, relying on imagination in such cases. We argue that there is little functional difference between empathy for a real, fictional, or absent person. The key element to consider in the presence of an emotionally-laden stimulus is that of perception and understanding in the observer, rather than actual emotionality in the target.

Additionally, a range of different emotions evoke empathy. ‘Negative empathy’ (e.g., pain / sadness) is often given prominence in the literature. For example, Batson et al. (1987, p.20) suggested empathy is “produced by witnessing another person’s suffering”. However, Fan, Duncan, de Greck, and Northoff (2011) identified a number emotions that can evoke empathy, including anger, anxiety, disgust, fear, happiness, pain, and sadness. Moreover, individuals may not have the same empathic capacity for different emotions (Eisenberg, 1986). For example, individuals may react strongly to ‘positive empathy’ (e.g., empathy for happiness), but dampen negative empathy to minimise personal distress.

Self-other Distinction or Merging?
It is also important to examine the internal self-oriented factors. Some conceptualisations\textsuperscript{10, 14, 34, 36} maintain a clear self-other distinction: the observer is aware that his/her emotional experience comes from an external source (de Vignemont & Singer, 2006). None of the conceptualisations identified here state that the observer does not have this awareness.

The main argument for a self-other distinction comes from the need to separate empathy from related concepts. In particular, this distinction is what separates empathy from emotional contagion (Decety & Lamm, 2006; de Vignemont & Singer, 2006; Gerdes et al., 2010; Scheler, cited in Ickes, 2003). With empathy, the observer is aware that this feeling is a result of perceiving emotion in the other. With emotional contagion, the emotion is captured but the observer lacks this awareness and the observer believes this feeling to be his/her own.

Neuroscientific evidence has demonstrated that observing another’s pain activates the observer’s brain areas responsible for pain (Singer & Lamm, 2009), reflecting some self-other merging. Jackson, Brunet, Meltzoff, and Decety (2006) reported the results of an fMRI study that demonstrated others’ experiences are processed the same as our own, but the degree of activation in relevant brain areas depends upon the degree of separation (i.e., greater activation when taking a ‘self-perspective’ compared to an ‘other-perspective’). Therefore, due to these shared processing systems some merging is evident. This merging aids empathy by providing a bridge between the self and other (Decety & Sommerville, 2003) and without some self-other merging it would be difficult to understand the other’s emotion (i.e., cognitive empathy).

**Trait or State Influences?**

Over a quarter of the conceptualisations we identified\textsuperscript{1, 4, 8, 9, 14, 15, 16, 20, 28, 31, 37} denoted empathy as an “ability” or “capacity”, implying a stable trait concept. However, others
suggest that empathic responses may be context specific (i.e., state influences), using words such as *situation*\(^1\)\(^,\)\(^2\)\(^3\), or *context*\(^8\). The trait view implies that some individuals are more empathic than others, with this ability being stable across time. Anatomical differences (Banissy, Kanai, Walsh, & Rees, 2012), as well as both genetic and developmental factors (Eisenberg & Morris, 2001), account for some variability in empathic abilities. Further support emerges from studies into the deficits found in autistic and psychopathic individuals. Other effects of dispositional factors such as gender (e.g., Derntl et al., 2010) and education (Thomas, Fletcher, & Lange, 1997) have been reported.

Thus, there is little doubt that empathic responding is subject to trait, individual difference factors. Nevertheless, considerable evidence supports the importance of situational, ‘state’ factors. For example, sex offenders do not have generalised empathy deficits, but are able to avoid empathy for certain individuals or groups of people (Fernandez, Marshall, Lightbody, & O’Sullivan, 1999). Similarly, violent men have decreased empathic accuracy towards their spouses, compared to female strangers (Clements, Holtzworth-Munroe, Schweinle, and Ickes, 2007). Moreover, a number of situational factors have been demonstrated to influence empathic responding, such as observer-target similarity (Eklund, Andersson-Stråberg, & Hansen, 2009), how much the observer values the target (Batson, Eklund, Chermok, Hoyt, & Ortiz, 2007), mood (Pithers, 1999), blame (Rudolph, Roesch, Greitemeyer, & Weiner, 2004), perceived power (Galinsky, Magee, Inesi, & Gruenfield, 2006), perceived need (Lishner et al., 2011), and cognitive load (Rameson, Morelli, & Lieberman, 2012). Thus, the evidence suggests that empathy is a result of the interaction between state and trait influences.

### Has a Behavioural Outcome?
Another contention is whether empathy necessarily has a behavioural outcome. Although evidence suggests that empathy is often followed by a behavioural response (Eisenberg & Miller, 1987), several authors have argued that empathy has no associated behavioural outcome in the immediate sense. A few definitions, contain behavioural responses to empathy and several stage models of the empathic process contain some form of behavioural outcome (e.g., Betancourt, 1990; Marshall et al., 1995). The singular concept of empathy, however, is typically located at an earlier stage, suggesting the separation of empathy from response behaviours. For example, Polaschek (2003) argued that empathy may be felt without an associated behavioural response in cases of competing interests or situational factors (e.g., when action would cause danger to the self). Others have argued that behaviour is evoked by empathy only when mediated through sympathy (e.g., de Vignemont & Singer, 2006; Eisenberg et al., 1999), which is supported by experimental evidence (Lishner et al., 2011). Furthermore, helping behaviours can precede empathy, such as in cases of emergency (Pithers, 1999).

The evidence therefore suggests that although empathy often leads to behavioural outcomes, this is not always the case, and such behavioural outcomes may be mediated through other factors. We suggest, therefore, that it is more appropriate to acknowledge this element as being a behavioural motivation (see Hills, 2001), rather than having a direct behavioural component, due to those examples of non-action presented above.

A further point to note is that empathy is not necessarily accompanied by a prosocial or helpful behavioural response. While empathy is normally associated with prosocial behaviours (perhaps due to lay use of the term; Hodges & Biswas-Diener, 2007), this is not always the case. For example, a good understanding of another’s emotions can be used by psychopaths to manipulate their victims (Hart, Cox, & Hare, 1995), or used by businesspeople to undermine competitors (Hodges & Biswas-Diener, 2007).
**Automatic or Controlled?**

One final discussion point, although largely ignored in conceptualisations of empathy is whether empathy is automatically elicited or subject to control. Hodges and Wegner (1997, p.312) argued that empathy, like other states of mind, “can be produced by variables beyond our control”. Indeed, neuroscientific studies suggest that empathy is automatically activated upon perception of an emotional other (Singer, Kiebel, Winston, Dolan, & Frith, 2004). However, empathy is a state of mind that we can reflect upon, control, and modify (Hodges and Wegner, 1997), using methods such as reframing (altering one’s perspective or cognitions), suppression (not thinking about the situation), and exposure control (avoiding emotional situations); all of these require cognitive effort (Hodges & Biswas-Diener, 2007). Thus, the evidence suggests the influence of both automatic and controlled processes on empathy.

**Summary**

The conclusions from the above discussions can be summarised as follows: There are functional differences between empathy and related concepts; empathy includes both cognitive and affective elements; the emotions of the target and observer are similar but not identical; other stimuli, such as imagination, can evoke empathy; a self-other distinction is maintained in empathy, although a degree of merging is necessary; empathy is affected by both trait and state influences; behavioural outcomes are not part of empathy itself; and finally, empathy is automatically elicited but is also subject to top-down controlled processes. Based upon an examination of these conclusions, we define empathy as follows:
Empathy is an emotional response (affective), dependent upon the interaction between trait capacities and state influences. Empathic processes are automatically elicited but are also shaped by top-down control processes. The resulting emotion is similar to one’s perception (directly experienced or imagined) and understanding (cognitive empathy) of the stimulus emotion, with recognition that the source of the emotion is not one’s own.

Consistent with the arguments above, our definition acknowledges the importance of both cognitive and affective factors, whilst qualifying emotional congruency based upon the accuracy of perception and cognitive understanding. Imagined stimuli are also acknowledged, as are the influences of both state and trait factors, and both automatic and controlled processes. The self-other distinction is identified but avoidance of the word ‘clear’ leaves room for a degree of merging. Although it is to be noted that empathy may lead to behavioural outcomes, this definition of empathy purposefully avoids behavioural implications. Care has also been taken to avoid confusion with related concepts such as sympathy.

Implications

The purpose of this paper was to raise awareness of the above issues, in an effort to develop a more widely shared understanding of empathy. Variations in conceptualisations have led to several issues. For example, early measurement scales are often criticised for the use of purely affective (e.g., Mehrabian & Epstein, 1972) or cognitive (e.g., Hogan, 1969) conceptualisations and for measuring constructs other than empathy (Joliffe & Farrington, 2006). Using a single definition will enable researchers to develop measures that conform to a shared understanding, allowing easier comparison between scales and study outcomes (Brown, Walker, Gannon, & Keown, 2013). Similarly, a clearer (and agreed upon)
conceptualisation of related terms may allow for a clear distinction between such concepts, again allowing us to more easily interpret and compare research outcomes. Additionally, better understanding of the themes discussed here may promote research into situational factors that contribute to empathy, the range of stimuli that may elicit empathy, and the range of emotions that may elicit empathy (e.g., joy, pride).

Conceptualising empathy and related concepts with greater clarity can also benefit practitioners. For example, Mann and Barnett’s (2012, p.2) discussion suggests differences between practitioners’ and researchers’ conceptualisations of empathy, perhaps explaining the widespread implementation of empathy treatment programmes for offenders, despite a lack of research evidence for doing so. Future research could examine the differences in how researchers and practitioners define empathy and related concepts, and examine what exactly practitioners wish to change/develop in offenders. For example, it might be that perspective taking is a greater treatment need than empathy.

A clear distinction between empathy and sympathy, potentially achieved by clarity in definitions, also has importance in clinical education and practice. For example, Clark (2010, p.95) stated that there are “qualitative differences” between empathy and sympathy, with each of these factors having benefits under different contexts. Clark summarises his discussion by suggesting that “a counselor’s awareness of the appropriate use of empathy and sympathy has potential to foster therapeutic gain” (p.100). Nightingale et al. (1991) provided medical physicians with a written vignette describing a patient who is upset, and asked them to respond either in an empathic (“I understand how you feel”) or a sympathetic (“I feel sorry for you”) manner. Those taking the more sympathetic approach to practice made greater use of hospital resources than those with an empathic approach. A clear understanding of the functional differences between sympathy and empathy in medical contexts may therefore
EMPATHY: A REVIEW OF THE CONCEPT

have implications in medical education, when trying to optimise physicians’ approaches to practice.

Conclusion

A new conceptualisation of empathy has been constructed based on careful consideration of previous conceptualisations, empirical evidence, and arguments presented by various authors in the field. Few authors to date have approached this task in such a way. By constructing an understanding of empathy through more informed approaches, we can make some headway into reducing the confusion that has plagued empathy research for more than a century, and pave the way for greater consistency in clinical practice. If empathy is defined using a more consistent approach, both research and practice will be enhanced as practitioners and researchers will be working with shared understandings of these complex concepts. This will allow greater comparability between research findings, promote research in often overlooked areas, and enhance the theoretical grounding for clinical interventions and measurement.
